

Access layer directly connected to core switch

Overview

The distribution layer connects the access layer to the core layer. When designing a campus LAN, you may. At present, we're using L2 VLAN trunks between the core and access. Some concerns I have with his argument are: * We're used to using L2 VLAN trunks * The L2 design is fairly simple * The end users are not "sensitive" enough to feel a failover of links from one core switch to another when a trunk. Each layer is served by specialized switches, with the access switch connecting end-user devices, the distribution switch aggregating traffic and enforcing policies, and the core switch acting as the high-speed backbone. The core switch is highly scalable, meaning it can be expanded as needed by simply adding more ports or modules.
