

The fastest operating time for a relay protection device

Overview

The decades of advancements of protection devices (from electromechanical to modern numerical relays) have allowed a significant reduction in protection operate time, from tens of milliseconds down to almost zero. The faster the protection operates, the smaller the resulting hazards, damage and the thermal stress will be. Further, the duration of the voltage dip caused by the short circuit fault will be shorter, the faster the protection operates. It is always advisable to plot the curves of relays and other protection devices, such as fuses. Its defining feature is zero intentional time delay (or minimal delay), with typical operating times of 20–50 ms, complying with IEC 60255-151 (Overcurrent Protection Standards) and IEEE C37.91 (Guide for Protection Relay Applications). Note: When it can be determined from the design of the circuit and the overcurrent devices involved that the automatic operation of a device was caused by an overload rather than a. We review traditional performance measures, such as transient overreach for distance zone 1, and formalize other measures, such as operating time and dependability.
