

Why can a single core of an optical fiber cable enable communication

Overview

In single-mode fibre, the core is so small — only about $8\text{ }\mu\text{m}$ in diameter — that light can only propagate in one transverse mode. These fibres are used for long-distance links because they minimise dispersion, the spreading of light pulses over distance. Fiber-optic communication is a form of optical communication for transmitting information from one place to another by sending pulses of infrared or visible light through an optical fiber. The light is a form of carrier wave that is modulated to carry information. Generally, glass, or sometimes plastic, is the material of choice since it ensures minimum signal attenuation while providing long-distance, high-speed. Single-Core Fiber refers to the traditional optical fiber that contains a single core through which light is transmitted. This cylindrical structure is typically composed of ultra-pure glass, often silicon dioxide, or sometimes specialized plastic, chosen for its clarity and minimal.
